To understand the darwinian theory of evolution :

- ▶ Theoretical basement,
- ▶ and History.
- ▶ problèmes.

The following talk is Gayon 1991.

Introduction

The Theory of Evolution

Descent with
modifications
Natural Selection

principles and
History

Simon Carrignon

ENS - P7 -
LAREMI - DEoM

For Darwin it's a :

Theory of descent with modification by variation and Natural Selection

Two components :

- ▶ Descent w/ Modification : random variation & heredity.
- ▶ Hypothesis of natural selection : "survival of the fittest" (Spencer's words).

Finally we have : a theory which explains how species change & diverge

Introduction

Nowaday issues

Level and unit of
selection
Population
darwinienne

Conclusion

Descent with modifications

The Darwin's theory of evolutions is built on

- ▶ parents to offsprings transmission of characters,
- ▶ character's variations.

That's what Darwin call *descent with variation*.

In Darwin's time :

- ▶ No theory of heredity !

But Darwin admit some properties to variations : they have to be *random* and *gradual* (quasi continue variations).

selection
Population
darwinienne

Conclusion

This characterisation of the variation raise numerous problems that Jenkin show :

- ▶ If variation is as Darwin want it :
 - ▶ no new characters' fixation
 - ▶ no evolution.
- ▶ the most serious critic for Darwin.

This has the woth to :

- ▶ Raise statistic as a tool to study Biology.
- ▶ Engage Biologist to focus on the origin of variations.

Conclusion

The Natural Selection Hypothesis

Theory of
Evolution :
principles and
History

Simon Carrignon

ENS - P7 -
LAREMI - DEoM

The Hypothesis : *if* descent with modification and restricted resources so :

Survival of the fittest (Spencer 1864)

, il la *Natural Selection* can act.

Problem : hard to prove (Darwin won't).

To strengthen it, Darwin develop :

- ▶ Analogy with Artificial Selection : if AS allow races modification, so SN does.

→ A strong of evolution but lacking of proof and empirical support.

Conclusion

Biometricians

School initiated by Galton (Darwin's cousin), performing between 1890 - 1916 : Pearson, Weldon.

Aims : prove the action of Natural Selection.

- ▶ “Mathematical (Statistical) Proof.
- ▶ Independent of any physiological theories.
- ▶ Really different philosophy (vs Darwin).

selection

Population
darwinienne

Conclusion

Beggining of XXe : rediscovery of Mendel's works (by de Vries) :

- ▶ no continu variations,
- ▶ hybridation of discontinuous traits
- ▶ evolution : jump & large mutation (saltationism)

In contradiction with Darwin :

→ species appear with large mutations, by “jumps” : not by the action of Natural Selection .

Introduction

Conclusion

Modern Synthesis

Reconciliate Mendel & Darwin through the genetic theory of evolution Fisher 1918, Haldane & Wright.

→ Population genetics.

Even between actors some vision are different :

- ▶ Fisher : Newton-like ideal “the Fundamental Theorem of Natural Selection”.
- ▶ Wright : local adaptation : the model of “Adaptative Landscapes”.

FIGURE 2.—Diagrammatic representation of the field of gene combinations in two dimensions instead of many thousands. Dotted lines represent contours with respect to adaptiveness.

FIGURE 4.—Field of gene combinations occupied by a population within the general field of possible combinations. Type of history under specified conditions indicated by relation to initial field (heavy broken contour) and arrow.

Years of synthesis : all biological related domains are rattaché to the genetic theory of evolution (30's 60's).

Conclusion

Modern synthesis, emergence of a consensus

- ▶ Biological individual are the product of genetical information transmitted by the germ line (Followin Weisman and central dogma) :

DNA→transcription→traduction→protein

- ▶ Genetical information spread from G^- to G^- via DNA which randomly vary.
- ▶ Evolution is change in allele frequencies.

Level and unit of selection

Lewontin (1972) :

In a population,

1. indiv. \neq \rightarrow morpho., physio., behavior \neq (**phenotypic variation**).
2. phenotypes \neq \rightarrow survival or reproductive rates \neq in \neq env. (**differential fitness**).
3. correlation btw parents & offsprings each G^- futur (**fitness heredity**).

This definition don't impose a level of biological organisation.

So which one is the right one ? (gene, chromosomes, organism, organes, species...) ?

Different approach of the pb (Gould : human cognitive limitation)

- ▶ Hull-Dawkins : replicator/interactor.
- ▶ Superorganism (Wilson & Sober).
- ▶ ...

Questions that have to be answered when applying Darwin to Musical structures.

Conclusion

Peter Godfrey-Smith thinks that “recipes” have problems

- ▶ Mix to hardly councilable goals :
 - ▶ “Universal”algorithm
 - ▶ Be able to describe every evolutives tales.

It's impossible, so : → Darwinian Population

1. Minimals (Lewontin's recipes)
2. Paradigmatics (clear multicell. orga. w/ sexual reproduction (Darwin analogy) ...)
3. Marginals

Conclusion

Figure: from PGS (2009, p.64)

Decomposition into sub properties, ideal frame to include radically different objects.

Conclusion

The questions handled by darwinian theory of evolution are huge and complexes. Export the theory out of its original bounds can be valuable for many reasons but one has always to keep in mind *what* he is trying to use and *how* he will use it.
